

Sprint #4 – Expected deliverables

This document outlines the requirements for the fourth sprint of the Software Engineering project.

To optimize time, we'll start with individual questions, where each team member will have 1 minute to describe what they did this sprint.

The following deliverables are expected:

1. Feature toggling implemented using Flagger for all new features added since the previous release until the day of the sprint. Remove also the flags/feature toggling from the previous releases within a single Pull Request. All Pull Requests related with feature toggling should be labelled as "category:toggling".
2. Infrastructure configuration managed through Terraform, ensuring reproducible and consistent environments (database, backend and frontend). The high availability should be possible with multiple container replicas (backend and frontend). All Pull Requests related with infrastructure management should be labelled as "category:terraform".
3. Observability implemented across the system, including:
 - Health checks in all containers.
 - Persistent structured logs should follow a structured logging methodology.
 - Defined SLOs/SLIs documented in docs/observability.md.
 - Observability implemented in the backend component (e.g., via OTLP / OpenTelemetry).
 - All Pull Requests related with observability should be labelled as "category:observability".
